ABSTRACT

Waste produced from end of useful life electrical and electronic equipment (EEE) denoted as e-waste, is one of the fastest waste streams worldwide. The growing amount of e-waste has caused a considerable challenge for policy makers to manage e-waste in an environmentally-sound mode in both developed and developing countries. Effective management of e-waste has become a global concern that is receiving growing attention due to the rapid increase in the quantity of e-waste. This mainly attributed to the rapid technology innovation and shortening product's useful lifespan coupled with tendency of people to keep up with the advanced technologies. This study compared and critically appraised three e-waste management models (producer responsibility, not-producer responsibility, and sharing responsibility) currently applied in Malaysia and the United States of America (USA), in an attempt to explore best management practices for the collection and treatment of e-waste that can be adopted in the Kingdom of Saudi Arabia. The data presented in this paper are secondary data obtained from a wide range of authoritative sources. This study recommends developing an e-waste national policy and regulatory framework to effectively manage the rapid growing rate of e-waste in the Kingdom of Saudi Arabia.

Keywords: E-waste production; E-waste management; E-waste recycling; Hazardous substance; Basel Convention; Recycling fee responsibility

1 Introduction

Advancement in technology is continuously influencing the lifestyle of the world's rising population. The demand of using new EEE is increasing while the useful life of these becomes

shorter. Widmer et al. (2005) reported that the average lifespan of a new model computer has dropped from approximately five years in 1992 to about two years in 2005. They also stated that cell phones start to malfunction after 2 to 3 years of use

compelling users to change to the latest version of the product incessantly. This suggests that e-waste has become one of the fastest streams of municipal solid waste generated (Dashkova, 2012). According to United Nations University, the estimated volume of electronic waste produced in 2016 is about 43 million tons, which is approximately 8% higher compared to 2014. Europeans produce 20 kg of e-waste per person each year, while USA inhabitants generate about 7 kg of e-waste per person per year (Namias, 2013). E-waste composition is different from one country to another. E-waste usually consists of a mixture of hazardous and valuable components, which are considered the most complex type of municipal waste generated on a continuous basis (Edwards, 2016). The management of e-waste is even more complex with the need for recycling and sustainable disposal of hazardous components. It is more critical in countries where there are less industries that manufacture EEE but use a wide range of products spanning different development ages imported over time. It is therefore important to survey the best international practices, especially in nations that carry out both the manufacturing and the effective management of EEE, to be adopted in developing countries that lacks the strengths of effective and efficient management of e-waste. This paper appraised the e-waste management practices currently applied in Malaysia and four states of the USA, in an attempt to extract some potential measures and suggest some recommendations to effectively manage the e-waste in the KSA.

2 Background and progress in e-waste management

2.1 The nature of e-waste and implications on health

E-waste is considered as substantially hazardous if managed irresponsibly and incorrectly. Inappropriate management of e-waste has a negative impact on the environment and can threaten human health. E-waste largely comprises of heterogeneous components, some of them are valuable materials while others contain toxic substances that can contaminate environmental media (water, air, and soil) and cause serious health problems (Vennila et al., 2014; UNESCO, 2017; Lang, 2018; Erin, 2019).

Routes of exposure and concentration of substances can therefore vary as suggested by Grant et al (2013) in Table 1.

Researchers (Dashkova, 2012) have noted cases of sending e-waste to landfill without appropriate treatment. The danger with such act is that heavy metals and other hazardous substance could be introduced to the soil and eventually to aquifers or other water reservoirs through leaching. Reclaiming resulting contaminated soil and water reservoirs can be expensive. Also, incinerating e-waste can release harmful gases that effect air quality (Dashkova, 2012). Guiyu, Hong Kong is a clear example of how e-waste is harmful on environment and human health. Guiyu, Hong Kong is considered as the largest site for e-waste dumping in the world (Watson, 2013). China appears to be the highest e-waste dump (e-waste basket) in the world. The United Nations banned e-waste transportation between countries but developed countries still export their e-waste to less privileged countries such as China and Vietnam illegally (Watson, 2013). Unsafe e-waste recycling and reuse can lead to discharges such as acids and sludge, which contaminate water sources.

Table 1: E-waste chemical components and electronic equipment, sources and routes of exposure (Grant et al., 2013; Ramachandra and Varghese, 2004)

Element	Component of electrical and electronic equipment	Ecological source of exposure	Route of exposure	Health implications
Lead	Printed circuit boards, cathode ray tubes, light bulbs, televisions (1.5-2.0 kg per monitor), and batteries	Air, dust, water, and soil	Inhalation, ingestion, and dermal contact	Toxic to brain and nervous systems Can lead to coma or death
Chromium	Anticorrosion coatings, data tapes, and floppy disks	Air, dust, water, and soil	Inhalation and ingestion	Asthmatic bronchitis. DNA damage
Cadmium	Switches, springs, connectors, printed circuit boards, batteries, infrared detectors, semi-conductor chips, ink or toner photocopying machines, cathode ray tubes, and mobile phones	Air, dust, soil, water, and food (especially rice and vegetables)	Ingestion and inhalation	Toxic irreversible effects on human health. Teratogenic Accumulates in kidney and liver. Causes neural damage.
Mercury	Thermostats, sensors, monitors, cells, printed circuit boards, and cold cathode fluorescent lamps (1-2 g per device)	Air, vapour, water, soil, and food (bio accumulative in fish)	Inhalation, ingestion, and dermal contact	Chronic damage to the brain. Respiratory and skin disorders due to bioaccumulation in fishes.
Zinc	Cathode ray tubes, and metal coatings	Air, water, and soil	Ingestion and inhalation	Cause of nausea, diarrhoea or vomiting
Nickel	Batteries	Air, soil, water, and food (plants)	Inhalation, ingestion, dermal contact, and transplacental.	Carcinogenic to lungs Cardiovascular disease Neurological defects High blood pressure

2.2 Management of e-waste

The hierarchy of e-waste management strategy (Figure 1) presents the ordering of waste management solutions from the most effective options to the least one. The five options of this general waste hierarchy are further explained in Table 2. Note that the ranking of waste management

options may differ in hierarchy in different countries. Most countries promote the three middle options in the hierarchy (re-use, recycle, and recovery), but some countries in the EU region are starting to adopt this general structure of waste management (avoidance/prevention) (Hamzah, 2011).

Figure 1: Waste Hierarchy Management (Laird, 2012).

Table 2: Waste Hierarchy Ranking and Description (Hamzah, 2011).

Option	Explanation
Avoidance/Prevention	Stay away from producing waste by reducing the volume of waste Design the equipment with less hazardous materials Increase the lifespan of the products
Re-use	Prepare the waste for reuse it again (cleaning, repairing and refurbishing), which will extend the lifetime of the item.
Recycling	Transferring the waste into new item, which reduces the amount of waste and conserves the resources at the same time.
Recovery	It can be by “incineration with energy recovery, gasification and pyrolysis which produce energy”.
Disposal	It is the last favourite option, which should be used when the waste cannot be recycled and the residual material after all previous options.

Another important aspect of e-waste management is the processing of the waste or scrap, common to all the management options. There are three main stages of managing the e-scrap: collection, sorting, and end processing (Namias, 2013). The first stage, Collection, may cover regional or national range. It is accomplished through recovery programs sponsored by the retail traders and manufacturers of electronics. Example of include municipal drop-off collection points, which could be non-profit and for-profit collection programs. This usually results in large heaps of e-waste, which need sorting. The second

stage is sorting which can be done both locally and nationally at different scales based on objectives. Processes may include further separation activities through magnetization, shredding materials and the eventual segregation into material streams of metals, glass and plastics. This stage may combine manual efforts and mechanical processes (Table 3) and helps to accomplish the separation of valuable components and the removal/safe disposal of hazardous items/substances. The end processing has some general application globally which entails the

recovery of precious components and cleaning them from any pollution.

Table 3: E-waste management process (Namias, 2013).

Stage	Stream	Process	Level
Collection	Equipment's	Manually	Regional or National
Sorting/dismantling and mechanical processing	Equipment's	Manually and Mechanical	Regional or National
End-processing	Material	Chemical	Global

2.3 Global scenes in e-waste management

Technology boom has continued to influence changes in lifestyle. The demand for electronic and electrical equipment has therefore increased. Thus, resulting in the increase of the amount of electronic waste especially with the decreasing in the life span of the equipment. The Global E-waste Monitor (2017), estimated e-waste amount produced in 2016 at about 44.7 million metric tons and projected to be 52.2 metric tons in 2021. However, most of e-waste ended up in landfill, incinerated or recycled under non-standard conditions (Balde et al., 2017). According to Balde et al (2017), the growth in e-waste can be attributed to:

- More people using the internet and online businesses from expanding internet access networks with faster broadband and wider coverage. According to Global E-waste Monitor (2017), almost half of the world's population are online using the internet. In addition, 4.2 billion people have active mobile-subscriptions broadband globally. While about 54% of households have internet access at home and 48% owns a computer.
- The electrical and electronic equipment in Global market is increasing continuously, but appliance useful lifespan is decreasing.

The lifespan of computers has dropped down from six years in 1997 to only two years in 2005 and the average lifecycle of phones is less than two years. This compels consumer to change and buy a new product continually.

- Many people own more than one connected appliance including phones, laptops, and e-readers. In the USA, it is suggested that everyone owns a phone.
- Consumers buy a new product to own latest version to keep up with technological advancements.

3 Research Design and Methodology

The method used in this research follows comparative case studies-based approach. The analysis of a set of international case studies enables the critical appraisal of some international practices on sustainable management of e-waste and identify best practices that could be applied in developing countries such as the Kingdom of Saudi Arabia. Three case studies (models) were examined. Model 1: producer responsibility (California State); Model 2: not-producer responsibility (Washington, Oregon, and New York); and Model 3: sharing responsibility (Malaysia). The research methodology is schematised in Figure 2. The analysis is divided into three phases. Phase 1: comparison between Model 1 and Model 2; Phase 2: comparison between Model 2 and Model 3; and Phase 3: comparison between Model 1 and Model 3. Best practices and procedures

extracted from the comparison between the three effectively and efficiently manage e-waste in the models are used to propose some measures to Kingdom of Saudi Arabia.

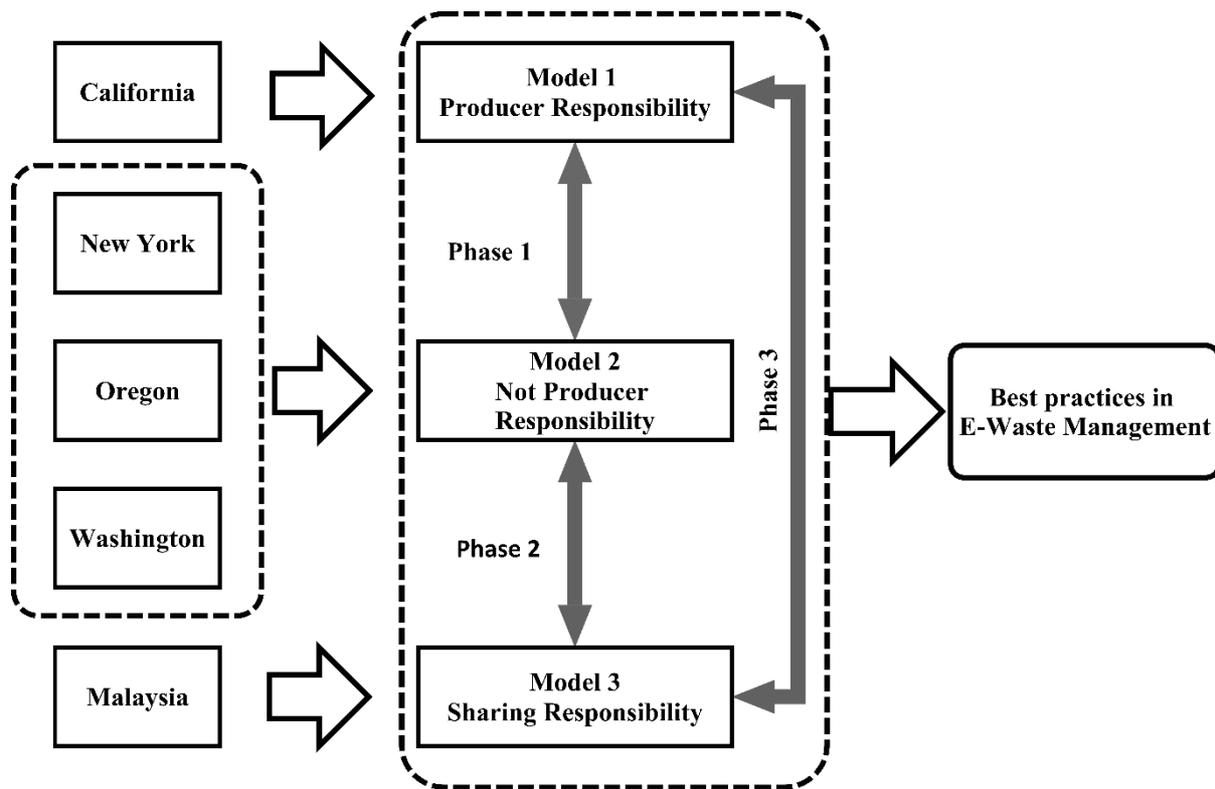

Figure 2. Research Approach

4 Research implementation

4.1 E-Waste Management in Saudi Arabia

The Chemical Safety and Hazardous Wastes department at the General Authority of Meteorology and Environment Protection is responsible for taking care of E-waste management in Saudi Arabia. The kingdom generates 378,000 tons of e-waste every year (Alameer, 2015). Saudi Arabia produced the highest amount of e-waste among Gulf Cooperation Council (GCC) Countries as indicated in Figure 3 (Alghozo and Ouda, 2016). The Gulf Cooperation

Council countries are Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and United Arab Emirates.

Saudi Arabia generates an enormous amount of e-waste and most of them end up in landfill. This creates a lot of environmental challenges in the country (Alameer, 2015) which constitute a cause for concern. The e-recycling rate (10-15%) is too low compared to the generated amount. In addition, recycling process is largely carried out by the informal sector and there are limited records that it is being done in the right way (Alghozo and Ouda, 2016).

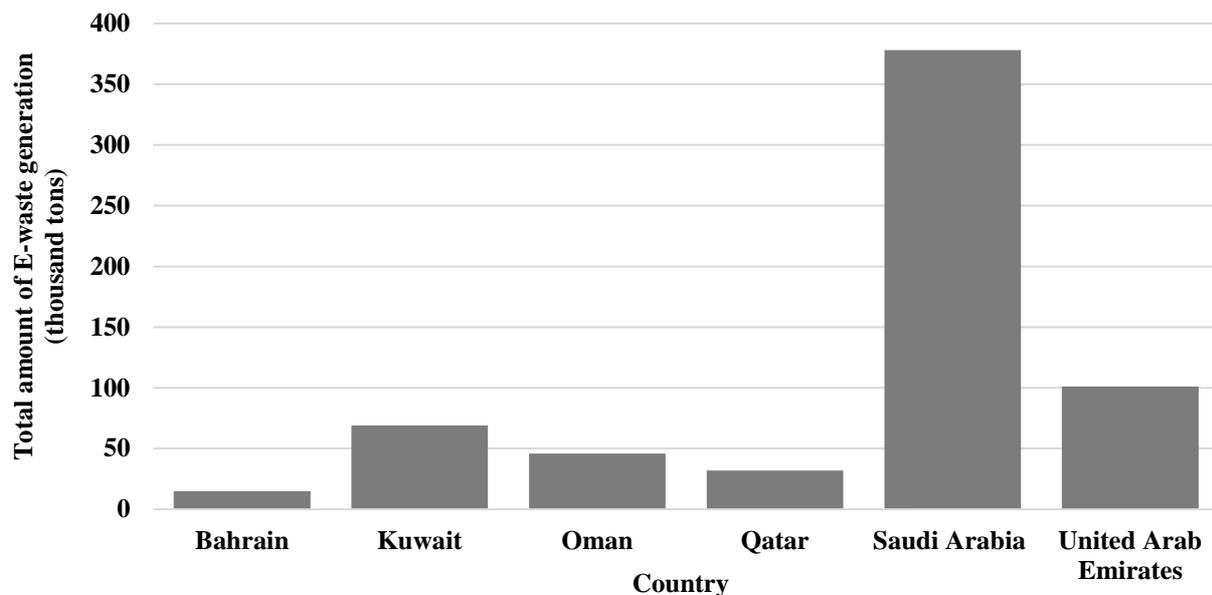

Figure 3: Total amount of e-waste generation in GCC countries in 2014 (Alghozo and Ouda, 2016).

According to Alameer (2015), there is no clear regulations on e-waste management in Saudi Arabia, but the country is starting to realise the need to tackle the challenge by taking appropriate actions towards adopting a sustainable e-waste management approach. The major challenges are that there is no proper method for e-waste handling (collection and transporting) and there is a very low public awareness about e-waste recycling (Alameer, 2015).

4.1.1. E-waste management in the USA

The USA ranked the second highest in producing e-waste after China (Richter, 2017). E-waste is suggested to be the fastest growing stream of municipal waste in USA because of people buying new versions of technology gadgets (Shumon et al., 2014). The US Environmental Protection Agency (EPA) states that around 80% to 85% of end life of electronic goes to landfill (Shumon et al., 2014).

Although the recycling rate for e-scrap appears to be increasing, a good proportion of the e-waste end up in landfill more than are recycled in the USA. Only 40% of e-waste generated in 2013 was recovered for recycling outside of the country, while the majority was trashed (landfill or incinerations). That means 40% was exported, which is a considerable amount (Electronics Take Back Coalition, 2019; EPA,

2019a). Note that about 25.3% of e-waste in the world was generated by the USA in 2016 (Balde et al., 2017). The main dumping site for US e-waste is Guiyu, China (Button, 2016).

Balde et al. (2017) reported that the United States of America (USA) still does not have a nation-wide e-waste management legislation, and instead has state regulations to manage e-waste. However, in the USA, measures such as Resource Conservation and Recovery Act (RCRA), were put in place, to prevent e-waste and to limit the negative effects posed by unappropriated disposal and treatment. Recently, placing electronics in the trash is illegal for most of US companies, and the disposal of electronics into municipal waste stream has been banned in some states (Namias, 2013). The first state to enact e-waste recycling legislation, Electronic Waste Recycling Act, is California in 2003. This legislation is inclusive of a broader waste ban and advance retrieval fee funding. Also, e-waste cannot be disposed in landfills or sent overseas (American Recycler News Inc., 2017).

(a) E-waste management in California

In order to attend to e-waste issues, the Electronic Waste Recycling Act of 2003 was ratified in

September 2003 in California as the first e-waste recycling legislation in United States (Bergner, 2004). The Electronic Waste Recycling Act of 2003 aims to decrease and minimize the use of perilous elements such as cadmium, lead, mercury and nickel in electronics devices that are sold in California (Namias, 2013). In addition, consumers who purchase some kinds of electronic equipment that contains cathode ray tubes (CRT), liquid crystal display (LCD) and plasma display devices, have been mandated to pay the waste recycling fee. The fee is collected by retailers who have the right to keep 3% of the amount to cover the costs of collection (Namias, 2013).

(b) E-waste management in Washington

The e-recycle program of Washington was established in 2006 (NCSL, 2018), to supply the residents with free e-waste recycle. Under this program, electronic manufacturers are responsible to offer e-recycling option to the customers with no additional cost. That means the companies that manufacture electronic devices are paid the recycling fee. After three years of commencing the program, the state began to recycle TVs, computers, and monitors. By 2013, tablet computers, e-readers and portable DVD players were added to the list.

(c) E-waste management in Oregon

In 2007, Oregon's Electronics Recycling Law established Oregon E-Cycles (NCSL, 2018). Oregon E-Cycles provides collection sites that accept up to seven electronic items at one time free of charge from households and small businesses. On the other hand, large businesses are required to pay recycling fee. However, Oregon E-Cycles does not offer free e-recycling for all electronic devices. Oregon prohibited the disposal of all computers, monitors and TVs as at 2010.

(d) E-waste management in New York

To ensure e-waste in New York is recycled appropriately, the New York State (NYS) Electronic Equipment Recycling and Reuse Act was established in May 28, 2010 (Department of Environmental Conservation, 2019). The act demands e-industrialist to provide electronic consumers (for residents and small businesses) with free recycling of their expired devices. While profit businesses with 50 or more full time employees might need to pay the recycling fee and not-for-profit corporations with 75 or more full time employees may be charged as well. According to NYS E-waste Recycling and Reuse Act report (2017), about 420 million pounds of e-waste from New York consumers were recycled or reused in an appropriate manner during the period of April 2011 to December 2015. Furthermore, it is considered as the most comprehensive and advanced e-waste legislation in the country (Department of Environmental Conservation, 2017). In addition, the study by Williams (2018) suggests that current e-waste stream has reduced from about 60% to 27 % in New York compared to 2005 quantities.

4.1.1 E-waste in Malaysia

Malaysia is classed as a developing economy. The country has been interested in environmental act and regulations since 1974 because of the attention on pollution from their early exploitation by palm oil mill and rubber mill industries. As time went on the concern extended to other sources of pollution as the country continued to develop through further industrialization, technology boom and the population growth. The environmental quality in Malaysia became a cause for concern (Isa, 2012). Although by the end of the 2010 decade, Malaysia is forecast to grow into the developed countries category, the need to combat e-waste is one primary aspect to overcome. The demand for using electronic equipment is increasing with growth in the economy and urbanization in the country (Zainu et al., 2015). Semarang (2016) stated that the estimated amount of e-waste generated in Malaysia in 2020 will be 53

million pieces, 3.5 times more than 1995 quantities. Note that the study looked at 6 devices: TV's, PC's, mobile phones, refrigerators, air conditions and washing machines (Semarang, 2016). However due to the significant amount of increasing e-waste, the study concentrated on the most challenging types of hazardous waste in the country (Zainu et al., 2015). Current suggestion is that the e-waste management programme in Malaysia should be developed as one of the vision 2020 objectives. That means Malaysia will not only be promoting economic and social aspects, but also the environmental aspects with regards to e-waste management (UKEssay, 2018). At the moment, e-waste management in Malaysia is mainly handled by private businesses with little government input. There also exist some e-waste recycling voluntary activities (Zainu et al., 2015). According to Hamzah (2011), Malaysia is one of the few countries that receive e-waste from USA. However, less developed countries such as India import e-waste from Malaysia. UKEssays (2018) reported that most of e-waste in Malaysia end up in landfill due to absence of or inadequate collection and disposal mechanism. Without proper management system, particularly in disposal processes, hazardous substances contained in e-waste can cause adverse effect to the surrounding environment and human health (Forti et al., 2018). An overview of current e-waste management in Malaysia (Masrom, 2017) indicates that it is a shared-responsibility. Recycling cost is shared between stakeholders, which means all e-waste stakeholders have to pay the recycling fee including companies that manufacture the devices, consumers, collectors and recyclers (Asian Region, 2014). According to the Asian Network Workshop (2017), the Japan International Cooperation Agency (JICA) technical cooperation in DOE is developing a project for new e-waste management mechanism. This project aims to apply a sustainable and environmentally sound e-waste management (collection and recycling) strategy (Masrom, 2017). The DOE issued 146 e-waste recovery facilities licenses in total; 18 of them

are full recovery facilities while 128 is for partial recovery (Suja et al., 2014).

The Malaysian government established a hazardous waste regulation in 1989. This was due to hazardous waste becoming a major issue in 1985s. In order to control the illegal hazardous waste movement, Malaysia joined Basel Convention in October 1993 (Isa, 2012). Malaysia has established a strict law on hazardous waste movement. The restriction is that no one can dispose, receive, and send e-waste in or out of Malaysia without any prior written approval of the Director General under the Basel Convention. If the law is violated, punishment includes the payment of RM 500,000 (equivalent to about 120,000 USD based on the 16th June 2019 currency exchange rate) or spend no more than five years prison (Isa, 2012). In addition, Royal Custom Department and Department of Environment is responsible for the control of hazardous waste movement at the entry point into the country. Consignment note is one the instrument used to detect illegal hazardous waste dumping. The hazardous waste movement also monitors Malaysia for generators, transporters and receivers of the waste movement. Furthermore, the government imposed all hazardous wastes handlers to use electronic-consignment note through web base application (Isa, 2012).

Never the less Malaysia still have challenges to resolve in e-waste management. These are describe as follows.

- Due to the geographical location of Malaysia (middle of international e-waste trade), she plays a key role in e-waste trading - as an importer and exporter and constitutes an international e-waste route movement that perpetrators use (Hamzah, 2011).
- There is no appropriate system of segregation and disposal of e-waste to encourage the enforcement of the public in recycling and appropriate discarding of e-waste (UKEssays, 2018).
- Inadequate infrastructure for e-waste management (UKEssays, 2018).

- Low economic of the country creates informal sector and illegal e-waste recycling, which is due to the scrambling for valuable e-waste components (Hamzah, 2011).

There are 7 categories of products covered in models 1 and 2 (Table 4). Although California commence e-recycle first but New York covered most products than others. This confirms that New York has the most comprehensive and progressive e-waste programme in the USA (Department of Environmental Conservation, 2017).

4.2 Findings and discussion from comparison

4.2.1 Phase 1 – comparison of models 1 and 2

(a) Scope of products covered

Table 4: Products covered in models of e-waste management

S/No	Product	USA				Malaysia
		California	Washington	Oregon	New York	
1	Computers, laptops, tablets, e- readers		Yes		Yes	Yes
2	TV	Yes	Yes	Yes	Yes	Yes
3	Small Scale Servers				Yes	Yes
4	Computer Peripherals ¹ ”(Keyboards, mice, faxes, scanners printers			Yes	Yes	Yes
5	Small Electronic Equipment (VCRs, DVRs, Portable Digital Music Players, DVD Players, Digital Converter Boxes, Cable or Satellite Receivers, Electronic or Video Game Consoles)”	Yes			Yes	
6	Refrigerator, A/C, Washing machine					Yes
7	Monitors	Yes	Yes	Yes		
	Total product categories	3	3	3	5	5

(b) The date of legislation declaration

As shown in Table 5, California is the first (2005) to declare the law on e-waste management, while the last is New York state in 2010. It is worth noting that it took 2-4 years after the date of enactment to implement the law.

(c) Recycling cost responsibility

Table 5 shows clearly that only the producer/manufacturers in California are responsible for the recycling e-waste fee. That is, the consumer pays the recycling fee at the time of product purchase. However, other states implement producer-responsibility for recycling fee.

(iv) Landfill disposal ban

Table 5 indicates that Washington has not yet banned disposal of e-waste totally whereas the rest of states have banned e-waste disposal even if it is a gradual process of effecting it.

4.2.2 Phase 2 - Comparison of models 1 and 3.

(a) The date of legislation declaration

Table 5 indicates that Malaysia signed e-recycle law in 2005 two years after California. However, there is great limitation of data from Malaysia so there is no recorded date of implementation. Malaysia does not follow a laid down approach to e-waste management. Also, it is noted from Table 5 that it took 2-4 years to

implement the laws after enacting them except for Malaysia.

(b) Scope of products covered

As seen from Table 5, California started e-recycling program before Malaysia but the recycling program in Malaysia covers a wider range of products. According to Panasonic (2018), the recycling rate of air conditions, refrigerator and washing machine is between 80% and 90% in Malaysia. These products are not covered in California.

(c) Recycling cost responsibility

California and Malaysia have different models of recycling fee responsibility as seen in Table 5. California focuses on the consumer paying for the recycling cost. Malaysia, on the other hand, shares the fee among stakeholders starting from consumers, manufactures and recyclers.

(d) Landfill disposal ban

Malaysia legislation has not banned the disposal for e-waste to landfill but California prohibited the disposal and it effected from 2001 (Table 5).

4.2.3 Phase 3 - Comparison will be between models 2 and 3.

(a) The date of legislation declared

Table 5 shows Malaysia is the first to establish the e-recycling law in 2005, but all states that signed into law after Malaysia have begun to implement the law on specific date. While the start date of implementation the law in Malaysia is not clear to date. In 2006, the legislation of e-recycling declared in Washington, Oregon followed and the last is New York in 2010.

(b) Scope of products covered

According to Table 5, most of e-waste products covered by New York State, and Malaysia ranked the second highest in scope of e-products covered in the recycling program. Washington and Oregon are in the middle. Only the Malaysia model covered refrigerator, A/C, washing machine.

(c) Recycling cost responsibly

Table 5 points out that Malaysia allows sharing the responsibility of the e-recycling cost, however, all electronic stakeholders should pay part of the recycling fee from consumers to recyclers. Note that other states are depending on the e-product producer to be charged for the recycling fee.

(d) Landfill disposal ban

Table 5 shows the ban of landfill disposal was progressively introduced in California recently, Oregon and New York also introduced a ban. Washington and Malaysia have not prohibited it, Most of e-waste in Malaysia ends up in landfill (UKEssays, 2018).

(e) Total amount of e-waste collected

For Model 2 (New York, Oregon, Washington). Due to the limitation of availability of data, it was difficult to access total e-waste collected in Malaysia in 2013, the amount is about (49752 tons) collected in New York jumped to almost a double amount is approximately (22410 tons) of the e-waste collected in 2011. Other states indicated slow increase in e-waste amount year by year (Electronics Take Back Coalition, 2013). The overall results of comparing the three models adopted by the 4 states in USA and Malaysia is summarised in Table 5.

Table 5: E-waste information of states/countries categorised into models

State/ Country	Recycle responsibility		Landfill disposal ban	Total e- waste data	Legislation		Model
	Free category	Paying category			Year signed	Year enforced	
California (USA)		The recycling fee paid by consumers at point of purchase. (Namias, 2013).	Yes	available	2003	2005	1 (Not producer or consumer responsibility)
Oregon (USA)	<ul style="list-style-type: none"> • Households • small businesses • small non-profits • Or anyone (even businesses) dropping off 7 items or less to collection points 	Producers to pay cost of recycling (collection, transportation, and sorting)	Yes	available	2007	2009	2 (Producer responsibility)
New York (USA)	<ul style="list-style-type: none"> • Individuals • Non-profits (<75 employees) • Schools • Government agencies • Small firms (< 50 employees) <i>Large non-profits and businesses may be charged</i> ".	Producers to pay cost of recycling (collection, transportation, and sorting)	Yes	Available	2010	2011	2 (Producer responsibility)
Washington (USA)	"Consumers, charities, small businesses, schools and small governments.	Producers to pay cost of recycling (collection, transportation, and sorting)	No	Available	2006	2009	2 (Producer responsibility)
Malaysia	Consumers are charged recycling fee at point of product purchase	Manufacturers pay Extended Producer Responsibility (EPR) fee while recyclers pay a registration fee	No	Not available	2005	No record	3 (Shared responsibility)

5 Conclusions and Recommendations

The growing amount of e-waste is gaining increasing interest and attention on the global agenda. E-waste is a fast-growing and complex waste stream because it contains a wide range of products. This makes it extremely difficult to manage. This study analysed and compared three international models of e-waste management currently adopted in California, Oregon, New York, Washington and Malaysia. The volume rates of e-waste are considerably increasing because of the rapid change in technologies and the tendency of people to acquire modern devices, which generates huge quantities of electrical and electronic wastes. Lack of proper management of e-waste puts the environment at risk and threaten the human health. Private companies, initiatives and Non-Profit-Organizations are currently working in the Kingdom of Saudi Arabia on e-waste recycling, however the current practice requires an adequately regulated system and concrete actions. Developing a sound regulatory framework to sustainably manage e-waste is highly recommended coupled with programs to increase consumer awareness for the importance of e-waste control and management in a safe and integrated system, which will reduce the environmental and health negative impacts of e-waste.
